FUNCTIONAL INTEGRATION, KONTSEVICH
INTEGRAL AND FORMAL INTEGRATION

LOUIS H. KAUFFMAN

Abstract. This paper is an exposition of the relationship between
Witten's functional integral and Vassiliev invariants.

1. Introduction

This paper shows how the Kontsevich Integrals, giving Vassiliev invariants in knot theory, arise naturally in the perturbative expansion of Witten’s functional integral. The paper is a sequel to [31]. Since the writing of [31] I became aware of the work of Labastida and Pérez [36] on this same subject. Their work comes to an identical conclusion, interpreting the Kontsevich integrals in terms of the light-cone gauge and thereby extending the original work of Fröhlich and King [14]. The purpose of this paper is to give an exposition of these relationships and to introduce diagrammatic techniques that illuminate the connections. In particular, we use a diagrammatic operator method that is useful both for Vassiliev invariants and for relations of this subject with the quantum gravity formalism of Ashtekar, Smolin and Rovelli [3]. An aspect that this paper does not treat is the perturbation expansion via three-space integrals leading to Vassiliev invariants as in [4]. See also [11]. Nor do we deal with the combinatorial reformulation of Vassiliev invariants that proceeds from the Kontsevich integrals as in [12].

The paper is divided into three sections. Section 2 discusses Vassiliev invariants and invariants of rigid vertex graphs. The section three on the functional integral introduces the basic formalism and shows how the functional integral is related directly to Vassiliev invariants. In this section we also show how our formalism works for the loop transform.
of Ashtekar, Smolin and Rovelli. Finally section 4 shows how the Kontsevich integral arises in the perturbative expansion of Witten’s integral in the axial gauge. One feature of section 4 is a new and simplified calculation of the necessary correlation functions by using the complex numbers and the two-dimensional Laplacian. We show how the Kontsevich integrals are the Feynman integrals for this theory. In a final section we discuss some of the possibilities of justifying functional integration on formal grounds.

**Acknowledgement.** It gives the author pleasure to thank Louis Licht, Chris King and Jurg Fröhlich for helpful conversations and to thank the National Science Foundation for support of this research under NSF Grant DMS-9205277 and the NSA for partial support under grant number MSPF-96G-179.

2. Vassiliev invariants and invariants of rigid vertex graphs

If $V(K)$ is a (Laurent polynomial valued, or more generally - commutative ring valued) invariant of knots, then it can be naturally extended to an invariant of rigid vertex graphs [26] by defining the invariant of graphs in terms of the knot invariant via an "unfolding" of the vertex. That is, we can regard the vertex as a "black box" and replace it by any tangle of our choice. Rigid vertex motions of the graph preserve the contents of the black box, and hence implicate ambient isotopies of the link obtained by replacing the black box by its contents. Invariants of knots and links that are evaluated on these replacements are then automatically rigid vertex invariants of the corresponding graphs. If we set up a collection of multiple replacements at the vertices with standard conventions for the insertions of the tangles, then a summation over all possible replacements can lead to a graph invariant with new coefficients corresponding to the different replacements. In this way each invariant of knots and links implicates a large collection of graph invariants. See [26], [27].

The simplest tangle replacements for a 4-valent vertex are the two crossings, positive and negative, and the oriented smoothing. Let $V(K)$ be any invariant of knots and links. Extend $V$ to the category of rigid vertex embeddings of 4-valent graphs by the formula

$$V(K_* = aV(K_+) + bV(K_-) + cV(K_0)$$
where $K_+$ denotes a knot diagram $K$ with a specific choice of positive crossing, $K_-$ denotes a diagram identical to the first with the positive crossing replaced by a negative crossing and $K^*$ denotes a diagram identical to the first with the positive crossing replaced by a graphical node.

This formula means that we define $V(G)$ for an embedded 4-valent graph $G$ by taking the sum

$$V(G) = \sum_S a^+(S)b^-(S)c^0(S)V(S)$$

with the summation over all knots and links $S$ obtained from $G$ by replacing a node of $G$ with either a crossing of positive or negative type, or with a smoothing of the crossing that replaces it by a planar embedding of non-touching segments (denoted 0). It is not hard to see that if $V(K)$ is an ambient isotopy invariant of knots, then, this extension is a rigid vertex isotopy invariant of graphs. In rigid vertex isotopy the cyclic order at the vertex is preserved, so that the vertex behaves like a rigid disk with flexible strings attached to it at specific points.

There is a rich class of graph invariants that can be studied in this manner. The Vassiliev Invariants [51],[10],[8] constitute the important special case of these graph invariants where $a = +1$, $b = -1$ and $c = 0$. Thus $V(G)$ is a Vassiliev invariant if

$$V(K_*) = V(K_+) - V(K_-).$$

Call this formula the exchange identity for the Vassiliev invariant $V$. See Figure 1

$V$ is said to be of finite type $k$ if $V(G) = 0$ whenever $|G| > k$ where $|G|$ denotes the number of (4-valent) nodes in the graph $G$. The notion of finite type is of extraordinary significance in studying these invariants. One reason for this is the following basic Lemma.

**Lemma.** If a graph $G$ has exactly $k$ nodes, then the value of a Vassiliev invariant $v_k$ of type $k$ on $G$, $v_k(G)$, is independent of the embedding of $G$.

**Proof.** The different embeddings of $G$ can be represented by link diagrams with some of the 4-valent vertices in the diagram corresponding
to the nodes of $G$. It suffices to show that the value of $v_k(G)$ is unchanged under switching of a crossing. However, the exchange identity for $v_k$ shows that this difference is equal to the evaluation of $v_k$ on a graph with $k + 1$ nodes and hence is equal to zero. This completes the proof. \hfill \square

The upshot of this Lemma is that Vassiliev invariants of type $k$ are intimately involved with certain abstract evaluations of graphs with $k$ nodes. In fact, there are restrictions (the four-term relations) on these evaluations demanded by the topology and it follows from results of Kontsevich [8] that such abstract evaluations actually determine the invariants. The knot invariants derived from classical Lie algebras are all built from Vassiliev invariants of finite type. All this is directly related to Witten’s functional integral [54].

In the next few figures we illustrate some of these main points. In Figure 2 we show how one associates a so-called chord diagram to represent the abstract graph associated with an embedded graph. The chord diagram is a circle with arcs connecting those points on the circle that are welded to form the corresponding graph. In Figure 3 we illustrate how the four-term relation is a consequence of topological invariance. In Figure 4 we show how the four term relation is a consequence of the abstract pattern of the commutator identity for a matrix Lie algebra.

**Figure 1 — Exchange Identity for Vassiliev Invariants**
This shows that the four term relation is directly related to a categorical generalisation of Lie algebras. Figure 5 illustrates how the weights are assigned to the chord diagrams in the Lie algebra case - by inserting Lie algebra matrices into the circle and taking a trace of a sum of matrix products.

3. Vassiliev invariants and Witten’s functional integral

In [54] Edward Witten proposed a formulation of a class of 3-manifold invariants as generalized Feynman integrals taking the form $Z(M)$ where

$$Z(M) = \int DAe^{i\frac{k}{4\pi}S(M,A)}.$$

Here $M$ denotes a 3-manifold without boundary and $A$ is a gauge field (also called a gauge potential or gauge connection) defined on $M$. The gauge field is a one-form on a trivial $G$-bundle over $M$ with values in a representation of the Lie algebra of $G$. The group $G$ corresponding to this Lie algebra is said to be the gauge group. In this integral the ”action” $S(M,A)$ is taken to be the integral over $M$ of the trace of the Chern-Simons three-form $A \wedge dA + \frac{2}{3} A \wedge A \wedge A$. (The product is the wedge product of differential forms.)
Figure 3 — The Four Term Relation from Topology
Figure 4 — The Four Term Relation from Categorical Lie Algebra

$Z(M)$ integrates over all gauge fields modulo gauge equivalence (See [5] for a discussion of the definition and meaning of gauge equivalence.)

The formalism and internal logic of Witten’s integral supports the existence of a large class of topological invariants of 3-manifolds and associated invariants of knots and links in these manifolds.

The invariants associated with this integral have been given rigorous combinatorial descriptions [45],[50],[33],[39],[52],[29], but questions and conjectures arising from the integral formulation are still outstanding.
Specific conjectures about this integral take the form of just how it implicates invariants of links and 3-manifolds, and how these invariants behave in certain limits of the coupling constant $k$ in the integral. Many conjectures of this sort can be verified through the combinatorial models. On the other hand, the really outstanding conjecture about the integral is that it exists! At the present time there is no measure theory or generalization of measure theory that supports it. Here is a formal structure of great beauty. It is also a structure whose consequences can be verified by a remarkable variety of alternative means.

We now look at of the Witten integral in more detail and see how it implicates invariants of knots and links corresponding to each classical Lie algebra. In order to accomplish this task, we need to introduce the Wilson loop. The Wilson loop is an exponentiated version of integrating the gauge field along a loop $K$ in three space that we take to be an embedding (knot) or a curve with transversal self-intersections. For this discussion, the Wilson loop will be denoted by the notation $W_K(A) = \langle K | A \rangle$ to denote the dependence on the loop $K$ and the field $A$. It is usually indicated by the symbolism $tr(Pe^{i K A})$. Thus

$$W_K(A) = \langle K | A \rangle = tr(Pe^{i K A}).$$
Here the $P$ denotes path ordered integration - we are integrating and exponentiating matrix valued functions, and so must keep track of the order of the operations. The symbol $tr$ denotes the trace of the resulting matrix.

With the help of the Wilson loop functional on knots and links, Witten writes down a functional integral for link invariants in a 3-manifold $M$:

$$Z(M, K) = \int DA e^{(ik/4\pi) S(M, A)} tr(P e^{i K A})$$

$$= \int DA e^{(ik/4\pi) S} < K | A > .$$

Here $S(M, A)$ is the Chern-Simons Lagrangian, as in the previous discussion. We abbreviate $S(M, A)$ as $S$ and write $< K | A >$ for the Wilson loop. Unless otherwise mentioned, the manifold $M$ will be the three-dimensional sphere $S^3$.

An analysis of the formalism of this functional integral reveals quite a bit about its role in knot theory. This analysis depends upon key facts relating the curvature of the gauge field to both the Wilson loop and the Chern-Simons Lagrangian. The idea for using the curvature in this way is due to Lee Smolin [47] (See also [42]). To this end, let us recall the local coordinate structure of the gauge field $A(x)$, where $x$ is a point in three-space. We can write $A(x) = A^a_k(x) T_a dx^k$ where the index $a$ ranges from 1 to $m$ with the Lie algebra basis $\{T_1, T_2, T_3, ..., T_m\}$. The index $k$ goes from 1 to 3. For each choice of $a$ and $k$, $A^a_k(x)$ is a smooth function defined on three-space. In $A(x)$ we sum over the values of repeated indices. The Lie algebra generators $T_a$ are matrices corresponding to a given representation of the Lie algebra of the gauge group $G$. We assume some properties of these matrices as follows:

1. $[T_a, T_b] = if^{abc} T_c$ where $[x, y] = xy - yx$, and $f^{abc}$ (the matrix of structure constants) is totally antisymmetric. There is summation over repeated indices.

2. $tr(T_a T_b) = \delta_{ab} / 2$ where $\delta_{ab}$ is the Kronecker delta ($\delta_{ab} = 1$ if $a = b$ and zero otherwise).

We also assume some facts about curvature. (The reader may enjoy comparing with the exposition in [28]. But note the difference of conventions on the use of $i$ in the Wilson loops and curvature definitions.)
The first fact is the relation of Wilson loops and curvature for small loops:

**Fact 1.** The result of evaluating a Wilson loop about a very small planar circle around a point \( x \) is proportional to the area enclosed by this circle times the corresponding value of the curvature tensor of the gauge field evaluated at \( x \). The curvature tensor is written

\[
F_{rs}^a(x)T_a dx^r dy^s.
\]

It is the local coordinate expression of \( F = dA + A \wedge A \).

**Application of Fact 1.** Consider a given Wilson line \( < K|S > \). Ask how its value will change if it is deformed infinitesimally in the neighborhood of a point \( x \) on the line. Approximate the change according to Fact 1, and regard the point \( x \) as the place of curvature evaluation. Let \( \delta < K|A > \) denote the change in the value of the line. \( \delta < K|A > \) is given by the formula

\[
\delta < K|A > = dx^r dx^s F_{rs}^a(x) T_a < K|A >.
\]

This is the first order approximation to the change in the Wilson line.

In this formula it is understood that the Lie algebra matrices \( T_a \) are to be inserted into the Wilson line at the point \( x \), and that we are summing over repeated indices. This means that each \( T_a < K|A > \) is a new Wilson line obtained from the original line \( < K|A > \) by leaving the form of the loop unchanged, but inserting the matrix \( T_a \) into that loop at the point \( x \). In Figure 6 we have illustrated this mode of insertion of Lie algebra into the Wilson loop. Here and in further illustrations in this section we use \( W_K(A) \) to denote the Wilson loop. Note that in the diagrammatic version shown in Figure 6 we have let small triangles with legs indicate \( dx^i \). The legs correspond to indices just as in our work in the last section with Lie algebras and chord diagrams. The curvature tensor is indicated as a circle with three legs corresponding to the indices of \( F_{rs}^a \).

**Notation.** In the diagrams in this section we have dropped mention of the factor of \((1/4\pi)\) that occurs in the integral. This convention saves space in the figures. In these figures \( L \) denotes the Chern–Simons Lagrangian.

**Remark.** In thinking about the Wilson line \( < K|A > = tr(Pe^{\int_K A}) \), it is helpful to recall Euler’s formula for the exponential:
Figure 6 — Lie algebra and Curvature Tensor insertion into the Wilson Loop

\[ e^x = \lim_{n \to \infty} (1 + x/n)^n. \]

The Wilson line is the limit, over partitions of the loop \( K \), of products of the matrices \((1 + A(x))\) where \( x \) runs over the partition. Thus we can write symbolically,

\[ <K|A> = \prod_{x \in K} (1 + A(x)) \]

\[ = \prod_{x \in K} (1 + A_a^k(x)T_a dx^k). \]

It is understood that a product of matrices around a closed loop connotes the trace of the product. The ordering is forced by the one dimensional nature of the loop. Insertion of a given matrix into this product at a point on the loop is then a well-defined concept. If \( T \) is a given matrix then it is understood that \( T < K|A> \) denotes the insertion of \( T \) into some point of the loop. In the case above, it is understood from context in the formula that the insertion is to be performed at the point \( x \) indicated in the argument of the curvature.

**Remark.** The previous remark implies the following formula for the variation of the Wilson loop with respect to the gauge field:

\[ \delta <K|A> / \delta(A_a^k(x)) = dx^k T_a <K|A>. \]

Varying the Wilson loop with respect to the gauge field results in the insertion of an infinitesimal Lie algebra element into the loop. Figure 7 gives a diagrammatic form for this formula. In that Figure we use a
capital \( D \) with up and down legs to denote the derivative \( \delta / \delta (A^a_k(x)) \). Insertions in the Wilson line are indicated directly by matrix boxes placed in a representative bit of line.

**Figure 7 — Differentiating the Wilson Line**

**Proof.**

\[
\delta \langle K | A \rangle / \delta (A^a_k(x))
\]

\[
= \delta \prod_{y \in K} (1 + A^a_k(y) T_a d y^k) / \delta (A^a_k(x))
\]

\[
= \prod_{y < x \in K} (1 + A^a_k(y) T_a d y^k) [T_a d x^k] \prod_{y > x \in K} (1 + A^a_k(y) T_a d y^k)
\]

\[
= d x^k T_a < K | A >.
\]

**Fact 2.** The variation of the Chern-Simons Lagrangian \( S \) with respect to the gauge potential at a given point in three-space is related to the values of the curvature tensor at that point by the following formula:

\[
F^a_{rs}(x) = \epsilon_{rst} \delta S / \delta (A^a_t(x)).
\]

Here \( \epsilon_{abc} \) is the epsilon symbol for three indices, i.e. it is +1 for positive permutations of 123 and -1 for negative permutations of 123 and zero if any two indices are repeated. A diagrammatic for this formula is shown in Figure 8.

With these facts at hand we are prepared to determine how the Witten integral behaves under a small deformation of the loop \( K \).
Theorem. 1. Let $Z(K) = Z(S^3, K)$ and let $\delta Z(K)$ denote the change of $Z(K)$ under an infinitesimal change in the loop $K$. Then

$$\delta Z(K) = \left(\frac{4\pi i}{k}\right) \int dA e^{\left(\frac{ik}{4\pi}\right)S[Vol]T_aT_a < K|A>$$

where $Vol = \epsilon_{rst}dx^r dx^s dx^t$.

The sum is taken over repeated indices, and the insertion is taken of the matrices $T_aT_a$ at the chosen point $x$ on the loop $K$ that is regarded as the ”center” of the deformation. The volume element $Vol = \epsilon_{rst}dx^r dx^s dx^t$ is taken with regard to the infinitesimal directions of the loop deformation from this point on the original loop.

2. The same formula applies, with a different interpretation, to the case where $x$ is a double point of transversal self intersection of a loop $K$, and the deformation consists in shifting one of the crossing segments perpendicularly to the plane of intersection so that the self-intersection point disappears. In this case, one $T_a$ is inserted into each of the transversal crossing segments so that $T_aT_a < K|A>$ denotes a Wilson loop with a self intersection at $x$ and insertions of $T_a$ at $x+\epsilon_1$ and $x+\epsilon_2$ where $\epsilon_1$ and $\epsilon_2$ denote small displacements along the two arcs of $K$ that intersect at $x$. In this case, the volume form is nonzero, with two directions coming from the plane of movement of one arc, and the perpendicular direction is the direction of the other arc.
Proof.

\[ \delta Z(K) = \int DA e^{(ik/4\pi)S} \delta <K|A> \]
\[ = \int DA e^{(ik/4\pi)S} dx^r dy^s F_{rs}^a(x) T_a <K|A> \]
\[ = \int DA e^{(ik/4\pi)S} dx^r dy^s \epsilon_{rst} (\delta S/\delta (A^r_t(x))) T_a <K|A> \]
\[ = (\frac{-4\pi i}{k}) \int DA (\delta e^{(ik/4\pi)S} / \delta (A^r_t(x))) \epsilon_{rst} dx^rdy^s T_a <K|A> \]
\[ = (4\pi i/k) \int DA e^{(ik/4\pi)S} \epsilon_{rst} dx^rdy^s (\delta T_a <K|A> / \delta (A^r_t(x))) \]

(integration by parts and the boundary terms vanish)
\[ = (4\pi i/k) \int DA e^{(ik/4\pi)S} [Vol] T_a T_a <K|A>. \]

This completes the formalism of the proof. In the case of part 2., a change of interpretation occurs at the point in the argument when the Wilson line is differentiated. Differentiating a self intersecting Wilson line at a point of self intersection is equivalent to differentiating the corresponding product of matrices with respect to a variable that occurs at two points in the product (corresponding to the two places where the loop passes through the point). One of these derivatives gives rise to a term with volume form equal to zero, the other term is the one that is described in part 2. This completes the proof of the Theorem.

The formalism of this proof is illustrated in Figure 9.

In the case of switching a crossing the key point is to write the crossing switch as a composition of first moving a segment to obtain a transversal intersection of the diagram with itself, and then to continue the motion to complete the switch. One then analyses separately the case where \( x \) is a double point of transversal self intersection of a loop \( K \), and the deformation consists in shifting one of the crossing segments perpendicularly to the plane of intersection so that the self-intersection point disappears. In this case, one \( T_a \) is inserted into each of the transversal crossing segments so that \( T^a T^a <K|A> \) denotes a Wilson loop with a self intersection at \( x \) and insertions of \( T^a \) at \( x + \epsilon_1 \) and \( x + \epsilon_2 \) as in part 2. of the Theorem above. The first insertion is in the moving line, due to curvature. The second insertion is the consequence of differentiating the
self-touching Wilson line. Since this line can be regarded as a product, the differentiation occurs twice at the point of intersection, and it is the second direction that produces the non-vanishing volume form.
Up to the choice of our conventions for constants, the switching formula is, as shown below (See Figure 10).

\[ Z(K_+) - Z(K_-) = (4\pi i/k) \int DA e^{(ik/4\pi)S} T_a T_a < K_{ss} | A > \]

\[ = (4\pi i/k) Z(T^a T^a K_{ss}), \]

where \( K_{ss} \) denotes the result of replacing the crossing by a self-touching crossing. We distinguish this from adding a graphical node at this crossing by using the double star notation.

**Figure 10 — The Difference Formula**

A key point is to notice that the Lie algebra insertion for this difference is exactly what is done (in chord diagrams) to make the weight systems for Vassiliev invariants (without the framing compensation). Here we take formally the perturbative expansion of the Witten integral to obtain Vassiliev invariants as coefficients of the powers of \((1/k^n)\). Thus the formalism of the Witten functional integral takes one directly to these weight systems in the case of the classical Lie algebras. In this way the functional integral is central to the structure of the Vassiliev invariants.
3.1. The Loop Transform

Suppose that $\psi(A)$ is a (complex valued) function defined on gauge fields. Then we define formally the loop transform $\hat{\psi}(K)$, a function on embedded loops in three dimensional space, by the formula

$$\hat{\psi}(K) = \int DA \psi(A) W_K(A).$$

If $\Delta$ is a differential operator defined on $\psi(A)$, then we can use this integral transform to shift the effect of $\Delta$ to an operator on loops via integration by parts:

$$\hat{\Delta} \psi(K) = \int DA \Delta \psi(A) W_K(A)$$

$$= - \int DA \psi(A) \Delta W_K(A).$$

When $\Delta$ is applied to the Wilson loop the result can be an understandable geometric or topological operation. In Figures 11, 12 and 13 we illustrate this situation with diagrammatically defined operators $G$ and $H$.

We see from Figure 12 that

$$\hat{G} \psi(K) = \delta \hat{\psi}(K)$$

where this variation refers to the effect of varying $K$ by a small loop. As we saw in this section, this means that if $\hat{\psi}(K)$ is a topological invariant of knots and links, then $\hat{G} \psi(K) = 0$ for all embedded loops $K$. This condition is a transform analogue of the equation $G \psi(A) = 0$. This equation is the differential analogue of an invariant of knots and links. It may happen that $\delta \hat{\psi}(K)$ is not strictly zero, as in the case of our framed knot invariants. For example with

$$\psi(A) = e^{(ik/4\pi) \int tr(A^\wedge dA + (2/3) A^\wedge A^\wedge A^\wedge A)}$$

we conclude that $\hat{G} \psi(K)$ is zero for flat deformations (in the sense of this section) of the loop $K$, but can be non-zero in the presence of a twist or curl. In this sense the loop transform provides a subtle variation on the strict condition $G \psi(A) = 0$. 
In [3] and earlier publications by these authors, the loop transform is used to study a reformulation and quantization of Einstein gravity. The differential geometric gravity theory is reformulated in terms of a background gauge connection and in the quantization, the Hilbert space consists in functions $\psi(A)$ that are required to satisfy the constraints

$$G\psi = 0$$

and

Figure 11— The Loop Transform and Operators $G$ and $H$
Figure 12 — The Diffeomorphism Constraint

\[ H \psi = 0 \]

where \( H \) is the operator shown in Figure 13. Thus we see that \( \hat{G}(K) \) can be partially zero in the sense of producing a framed knot invariant, and (from Figure 13 and the antisymmetry of the epsilon) that \( \hat{H}(K) \) is zero for non-self intersecting loops. This means that the loop transforms of \( G \) and \( H \) can be used to investigate a subtle variation of the original scheme for the quantization of gravity. This program is being actively pursued by a number of researchers. The Vassiliev invariants arising from a topologically invariant loop transform should be of significance to this theory. This theme will be explored in a subsequent paper.

4. Wilson lines, axial gauge and the Kontsevich integrals

In this section we follow the gauge fixing method used by Fröhlich and King [14]. Their paper was written before the advent of Vassiliev
invariants, but contains, as we shall see, nearly the whole story about the Kontsevich integral. A similar approach to ours can be found in [36]. In our case we have simplified the determination of the inverse operator for this formalism and we have given a few more details about the calculation of the correlation functions than is customary in physics literature. I hope that this approach makes this subject more accessible to mathematicians. A heuristic argument of this kind contains a great deal of valuable mathematics. It is clear that these matters will eventually be given a fully rigorous treatment. In fact, in the present case
there is a rigorous treatment, due to Albevario and Sen-Gupta [2] of the
functional integral after the light-cone gauge has been imposed.

Let \((x^0, x^1, x^2)\) denote a point in three dimensional space. Change to
light-cone coordinates

\[
    x^+ = x^1 + x^2
\]

and

\[
    x^- = x^1 - x^2.
\]

Let \(t\) denote \(x^0\).

Then the gauge connection can be written in the form

\[
    A(x) = A_+(x)dx^+ + A_-(x)dx^- + A_0(x)dt.
\]

Let \(CS(A)\) denote the Chern-Simons integral (over the three dimensional
sphere)

\[
    CS(A) = (1/4\pi) \int tr(A \wedge dA + (2/3)A \wedge A \wedge A).
\]

We define axial gauge to be the condition that \(A_- = 0\). We shall now
work with the functional integral of the previous section under the axial
gauge restriction. In axial gauge we have that \(A \wedge A \wedge A = 0\) and so

\[
    CS(A) = (1/4\pi) \int tr(A \wedge dA).
\]

Letting \(\partial_{\pm}\) denote partial differentiation with respect to \(x^\pm\), we get the
following formula in axial gauge

\[
    A \wedge dA = (A_+ \partial_- A_0 - A_0 \partial_- A_+) dx^+ \wedge dx^- \wedge dt.
\]

Thus, after integration by parts, we obtain the following formula for the
Chern-Simons integral:

\[
    CS(A) = (1/2\pi) \int tr(A_+ \partial_- A_0) dx^+ \wedge dx^- \wedge dt.
\]

Letting \(\partial_i\) denote the partial derivative with respect to \(x_i\), we have that

\[
    \partial_+ \partial_- = \partial_1^2 - \partial_2^2.
\]

If we replace \(x^2\) with \(ix^2\) where \(i^2 = -1\), then \(\partial_+ \partial_-\) is replaced by

\[
    \partial_1^2 + \partial_2^2 = \nabla^2.
\]

We now make this replacement so that the analysis can be expressed
over the complex numbers.
Letting
\[ z = x^1 + ix^2, \]
it is well known that
\[ \nabla^2 \ln(z) = 2\pi \delta(z) \]
where \( \delta(z) \) denotes the Dirac delta function and \( \ln(z) \) is the natural logarithm of \( z \). Thus we can write
\[ (\partial_+ \partial_-)^{-1} = (1/2\pi) \ln(z). \]
Note that \( \partial_+ = \partial_z = \partial / \partial z \) after the replacement of \( x^2 \) by \( ix^2 \). As a result we have that
\[ (\partial_-)^{-1} = \partial_+ (\partial_+ \partial_-)^{-1} = \partial_+ (1/2\pi) \ln(z) = 1/2\pi z. \]
Now that we know the inverse of the operator \( \partial_- \) we are in a position to treat the Chern-Simons integral as a quadratic form in the pattern
\[ (-1/2) < A, LA > = -iCS(A) \]
where the operator
\[ L = \partial_- \]
Since we know \( L^{-1} \), we can express the functional integral as a Gaussian integral:
We replace
\[ Z(K) = \int D A e^{ikCS(A)} tr(P e^{f_K A}) \]
by
\[ Z(K) = \int D A e^{iCS(A)} tr(P e^{f_K A/\sqrt{k}}) \]
by sending \( A \) to \((1/\sqrt{k})A\). We then replace this version by
\[ Z(K) = \int D A e^{(-1/2) < A, LA >} tr(P e^{f_K A/\sqrt{k}}). \]
In this last formulation we can use our knowledge of \( L^{-1} \) to determine the the correlation functions and express \( Z(K) \) perturbatively in powers of \((1/\sqrt{k})\).

**Proposition.** Letting
\[ < \phi(A) > = \int D A e^{(-1/2) < A, LA >} \phi(A)/ \int D A e^{(-1/2) < A, LA >} \]
for any functional $\phi(A)$, we find that
\[
\begin{align*}
< A^a_+(z, t) A^b_+(w, s) > &= 0, \\
< A^a_0(z, t) A^b_0(w, s) > &= 0, \\
< A^a_+(z, t) A^b_0(w, s) > &= \kappa \delta^{ab} \delta(t - s)/(z - w)
\end{align*}
\]
where $\kappa$ is a constant.

**Proof Sketch.** Let’s recall how these correlation functions are obtained. The basic formalism for the Gaussian integration is in the pattern
\[
< A(z) A(w) >= \int D A e^{-1/2 <A, LA>} A(z) A(w) / \int D A e^{-1/2 <A, LA>}
\]
\[
= (\left. (\partial/\partial J(z)) (\partial/\partial J(w)) \right|_{J=0}) e^{(1/2) <J, L^{-1} J>}
\]
Letting $G * J(z) = \int dw G(z - w) J(w)$, we have that when
\[
LG(z) = \delta(z)
\]
($\delta(z)$ is a Dirac delta function of $z$) then
\[
LG * J(z) = \int dw LG(z - w) J(w) = \int dw \delta(z - w) J(w) = J(z)
\]
Thus $G * J(z)$ can be identified with $L^{-1} J(z)$.

In our case
\[
G(z) = 1/2\pi z
\]
and
\[
L^{-1} J(z) = G * J(z) = \int dw J(w)/(z - w).
\]
Thus
\[
< J(z), L^{-1} J(z) >= < J(z), G * J(z) >
\]
\[
= (1/2\pi) \int tr(J(z)) (\int dw J(w)/(z - w)) dz
\]
\[
= (1/2\pi) \int dz dw tr(J(z) J(w))/(z - w).
\]
The results on the correlation functions then follow directly from differentiating this expression. Note that the Kronecker delta on Lie algebra indices is a result of the corresponding Kronecker delta in the trace formula $tr(T_a T_b) = \delta_{ab}/2$ for products of Lie algebra generators. The
Kronecker delta for the $x^0 = t, s$ coordinates is a consequence of the evaluation at $J$ equal to zero. 

We are now prepared to give an explicit form to the perturbative expansion for 

$$< K > = Z(K) / \int DA e^{(-1/2)A,LA}$$ 

$$= \int DA e^{(-1/2)A,LA} tr(Pe^{\int K A/\sqrt{k}}) / \int DA e^{(-1/2)A,LA}$$ 

$$= \int DA e^{(-1/2)A,LA} tr(\prod_{x \in K} (1 + (A/\sqrt{k}))) / \int DA e^{(-1/2)A,LA}$$ 

$$= \sum_n (1/k^{n/2}) \oint_{K_1 < ... < K_n} < A(x_1)...A(x_n) > .$$ 

The latter summation can be rewritten (Wick expansion) into a sum over products of pair correlations, and we have already worked out the values of these. In the formula above we have written $K_1 < ... < K_n$ to denote the integration over variables $x_1,...,x_n$ on $K$ so that $x_1 < ... < x_n$ in the ordering induced on the loop $K$ by choosing a basepoint on the loop. After the Wick expansion, we get 

$$< K > = \sum_m (1/k^m) \oint_{K_1 < ... < K_n} \sum_{p=\{x_i < x_i'\}_{i=1,...,m}} \prod_i < A(x_i) A(x_i') > .$$ 

Now we know that 

$$< A(x_i) A(x_i') >= < A_a^a(x_i) A_b^b(x_i') > T_a T_b dx^k dx^l.$$

Rewriting this in the complexified axial gauge coordinates, the only contribution is 

$$< A_a^a(z,t) A_b^b(s,w) >= \kappa \delta^{ab} \delta(t - s)/(z - w).$$

Thus 

$$< A(x_i) A(x_i') >$$ 

$$= < A_a^a(x_i) A_b^b(x_i') > T_a T_b dx^+ \wedge dt + < A_a^a(x_i) A_a^a(x_i') > T_a T_a dx^+ \wedge dt$$ 

$$= (dz - dz')/(z - z')[i/i']$$
where \([i/i']\) denotes the insertion of the Lie algebra elements \(T_a T_a\) into the Wilson loop.

As a result, for each partition of the loop and choice of pairings \(P = \{x_i < x'_i | i = 1, ... m\}\) we get an evaluation \(D_P\) of the trace of these insertions into the loop. This is the value of the corresponding chord diagram in the weight systems for Vassiliev invariants. These chord diagram evaluations then figure in our formula as shown below:

\[
<K> = \sum_m \left(\frac{1}{k^m}\right) \sum_P D_P \oint_{K_1 < ... < K_n} \prod_{i=1}^{m} \frac{(dz_i - dz'_i)/((z_i - z'_i))}{(z_i - z'_i)}
\]

This is a Wilson loop ordering version of the Kontsevich integral. To see the usual form of the integral appear, we change from the time variable (parametrization) associated with the loop itself to time variables associated with a specific global direction of time in three dimensional space that is perpendicular to the complex plane defined by the axial gauge coordinates. It is easy to see that this results in one change of sign for each segment of the knot diagram supporting a pair correlation where the segment is oriented (Wilson loop parameter) downward with respect to global time direction. This results in the rewrite of our formula to

\[
<K> = \sum_m \left(\frac{1}{k^m}\right) \sum_P (-1)^{|P|} D_P \int_{t_1 < ... < t_n} \prod_{i=1}^{m} \frac{(dz_i - dz'_i)/((z_i - z'_i))}{(z_i - z'_i)}
\]

where \(|P|\) denotes the number of points \((z_i,t_i)\) or \((z'_i,t_i)\) in the pairings where the knot diagram is oriented downward with respect to global time. The integration around the Wilson loop has been replaced by integration in the vertical time direction and is so indicated by the replacement of \(\{K_1 < ... < K_n\}\) with \(\{t_1 < ... < t_n\}\).

The coefficients of \(1/k^m\) in this expansion are exactly the Kontsevich integrals for the weight systems \(D_P\). See Figure 14.

It was Kontsevich’s insight to see (by different means) that these integrals could be used to construct Vassiliev invariants from arbitrary weight systems satisfying the four-term relations. Here we have seen how these integrals arise naturally in the axial gauge fixing of the Witten functional integral.
Remark. The careful reader will note that we have not made a
discussion of the role of the maxima and minima of the space curve of
the knot with respect to the height direction \((t)\). In fact one has to
take these maxima and minima very carefully into account and to di-
vide by the corresponding evaluated loop pattern (with these maxima
and minima) to make the Kontsevich integral well-defined and actually
invariant under ambient isotopy (with appropriate framing correction
as well). The corresponding difficulty appears here in the fact that be-
cause of the gauge choice the Wilson lines are actually only defined in
the complement of the maxima and minima and one needs to analyse
a limiting procedure to take care of the inclusion of these points in the
Wilson line. This points to one of the places where this correspondence
with the Kontsevich integrals as Feynman integrals for Witten’s func-
tional integral could stand closer mathematical scrutiny. One purpose of
this paper has been to outline the correspondences that exist and to put enough light on the situation to allow a full story to eventually appear.

5. Formal integration

In light of the fact that many beautiful and rigorous results come forth from the formal manipulation of functional integrals, it is of interest to attempt to see whether one can create a formal (essentially combinatorial) category in which these manipulations can exist. This section is devoted to some very elementary remarks along this line.

Suppose that we start with an extended real line in the sense of Robinson’s non-standard analysis [44], [18]. (For a delightful introduction to a similar construction of an extended real line see also Conway’s work on Surreal Numbers [13].) In this line there are infinitesimals $\delta$ each less than any standard real and the extended line is still a field. Can we make formal integrals that make sense of Leibniz’s $\int_a^b f(x)dx$ as a "sum" over infinitely many small quantities?

The yoga for the usual Robinson approach is to define a Riemann sum $S(\Delta x) = \sum_{i=0}^{n} f(x_i)\Delta x$ where $\{x_0, ..., x_n\}$ is a partition of the interval $[a, b]$ and $n\Delta x = b - a$. The Riemann sum is regarded as a function of $\Delta x$, and then by the Robinson logic of transferring statements about reals to statements about hyperreals, one can let $\Delta x$ be infinitesimal to define the integral.

Here, I want to note that there is a very formal counterpart to this process that lets one define an indefinite "micro-integral" by a straightforward formula where $\delta$ is an infinitesimal:

$$F(x) = f(x)\delta + f(x - \delta)\delta + f(x - 2\delta)\delta + ...$$

I claim that $F(x)$ is a formal representative for $\int^x f(t)dt$. In particular, let’s compute the derivative of $F$:

$$F(x + \delta) = f(x + \delta)\delta + f(x)\delta + f(x - \delta)\delta + f(x - 2\delta)\delta + ...$$

Thus

$$(F(x + \delta) - F(x))/\delta = f(x + \delta).$$

Every finite hyperreal is a unique sum of a real and an infinitesimal. The derivative of a function is defined to the real part of the difference quotient using $\delta$. It follows that
\[ F'(x) = f(x). \]

In this sense, we can directly write down a formal antiderivative for a real-valued function \( f(x) \).

How far are we on the road toward writing down a formal version of a functional integral in gauge field theory? Is there a combinatorial formula for \( Z(M,K) = \int DA e^{i(k/4\pi)S(M,A)} tr(Pe^{iK \cdot A}) \) utilizing an orchestration of countable sums of infinitesimals from the hyperreals? If we do make such a construction it may, like our toy example \( F(x) \), be itself infinitesimal, or even infinite. The problem is to make it well-defined in the hyperreals and so that the typical results about integrating Gaussians are logical consequences of its construction. That is the question!

Since I do not have an answer to this question at this writing, let me add a few more ideas. There is another approach to the infinitesimal calculus due to Lawvere and Bell [7] that uses square zero infinitesimals. These are infinitesimals \( \epsilon \) such that \( \epsilon^2 = 0 \). Of course the extension of the reals to these new hyperreals is no longer a field. Furthermore these structures are usually wrapped in a cloak of intuitionistic mathematics and category theory (topos theory – see [7] and [40]). The intuitionism comes from the desire that \( \epsilon \) be indistinguishable from zero and yet not zero. Such subtlety is possible in a world where the double negative is distinct from an affirmation.

The square zero infinitesimals are charming. In this system, the formula
\[ f(x + \epsilon) = f(x) + f'(x)\epsilon \]
defines the derivative of \( f(x) \), and all the familiar properties of derivatives follow easily.

Now square zero infinitesimals remind the differential geometer immediately of Grassmann algebra and exterior differential forms. Actually there are two significant choices that one can make at this fundamental level. One can choose to assume that distinct square zero infinitesimals commute with one another, and do not necessarily annihilate each other
when multiplied. Or one can assume that they do not necessarily commute, but that the squares of any finite sum of them is itself of square zero. Let us consider these two choices one at a time.

In the case of commuting square zero infinitesimals $\alpha$ and $\beta$, we have

$$ (\alpha + \beta)^2 = \alpha^2 + 2\alpha\beta + \beta^2 $$

while

$$(\alpha + \beta)^3 = 0.$$ 

In general, the commutative situation forces higher and higher orders of nilpotency for sums of independent infinitesimals. An infinite sum of square zero infinitesimals can stand for a standard Robinson infinitesimal. This indicates that the Robinson theory should be seen as the limit of square zero theories. This is the analog of thinking of a Taylor series in terms of its truncations.

In the case of all sums having square zero and non-commutation, we recover an infinitesimal version of Grassmann algebra:

$$ 0 = (\alpha + \beta)^2 = \alpha^2 + \alpha\beta + \beta\alpha + \beta^2 $$

Thus

$$ 0 = \alpha\beta + \beta\alpha. $$

I take these elementary observations as hints that the correct version of calculus for our purposes will contain infinitesimals that partake of all these options, and that we should press ahead and create the theory that contains them.
